# Clinical Care Guidelines for: Major Depression in Adults

## DSM-5 Diagnostic Criteria

5 or more symptoms present during a 2 week period; (1) depressed mood or (2) loss of interest or pleasure and any three of the following:

- Significant weight loss or decrease in appetite
- Insomnia or hypersomnia
- Psychomotor agitation or retardation
- Fatigue or lack of energy
- Feelings of worthlessness or guilt
- Decreased concentration or indecisiveness
- Recurrent thoughts of death or suicide

Symptoms cause significant distress or impairment in functioning and not due to significant loss or change in life, absence of manic/hypomaniac episodes.

The PHQ9 is recommended for screening and treatment monitoring.

## Rule Out/Monitor Co-Occurring Medical Conditions

- Ensure that a general medical evaluation has been completed
- Evaluate functional impairment and quality of life

### Assess for Suicidal Ideation/Crisis

- If the patient has a plan, the means or has recently attempted, hospitalize
- If the situation is unclear and the patient is being evaluated by a medical provider, refer to a behavioral health practitioner
- Evaluate level of impulsivity and if patient can commit to not harming himself; seek help if the ideation becomes overwhelming
- Refer to a psychiatrist or behavioral health professional if symptoms are severe, there are co-morbid conditions, there are significant psychosocial stressors, and/or substance abuse
- Assess level of self-care (nutrition, hydration, ADLs)
- Establish the least restrictive environment for treatment and evaluate frequently for any need to change the level of care

## Treatment

### Medication Management

If symptoms are moderate to severe, evaluate for medication.

If medication is prescribed, patient should be seen within 1–4 weeks to assess and adjust.

At least 12 weeks continuous treatment in the acute phase.

At least one additional visit after the 4 week check in the next 4–8 weeks.

For effective continuation phase of treatment, monitor medication for the next 6 months. Visits may be less frequent.

To prevent relapse after symptom remission, stay on medication an additional 6–12 months.

Maintenance (greater than 9 months) for patients with a history of chronic symptoms, 3 or more episodes of depression, severe episodes, episodes beginning prior to age 20, or family history of bipolar disorder. Monitor at regular intervals and assess for re-emergence of symptoms. May require an additional 15–28 months on medication.

If discontinuing medication, taper slowly over several weeks and monitor for recurrence of symptoms.

Coordinate care with other clinicians involved in care.

Provide education to the family and patient.

### Psychottherapy

Cognitive behavioral therapy or individual interpersonal therapy–outpatient.

Therapy alone may be used for mild to moderate symptoms.

Frequency depends on the severity of the illness.

For moderate to severe symptoms, should be used in combination with medication.

Regular exercise and education regarding depression are recommended as adjuncts to treatment.

Severe symptoms, decline in functioning and/or suicidal ideation/ intent may require a higher level of care.

If patient is discharged from inpatient hospitalization, patient needs to be seen in an outpatient setting, intensive outpatient setting or partial hospitalization by a behavioral health provider within 7 calendar days.

As depression symptoms remit, less frequent therapy sessions would be appropriate to maintain stability.

ECT is appropriate for severe depression that hasn’t responded to numerous medications and/or therapy and who have significant functional impairment.
Antidepressant medications are grouped into the following classes:

1. Tricyclic Antidepressants (TCAs)
2. Select Serotonin Reuptake Inhibitors (SSRIs)
3. Serotonin and Norepinephrine Reuptake Inhibitors (SNRIs)
4. Atypical Antidepressants
5. Monoamine Oxidase Inhibitors (MAOIs)
6. Norepinephrine Reuptake Inhibitor (NRI)
7. Dopamine Agonist (DA)

The effectiveness of antidepressant medications is generally comparable between classes and within classes of medications. Response rates typically range from 50% to 75% among all classes and agents. Antidepressants do differ in their potential to cause particular side effects such as adverse sexual effects, sedation, or weight gain. Because of this, the initial selection of an antidepressant medication regimen should strongly consider the tolerability, safety, and cost of the medication, as well as patient preference and history of prior medication treatment. Second-generation antidepressants, which include the SSRI, SNRI and Atypical Antidepressant classes are optimal and usually preferred for most patients over the older medications in the TCA and MAOI classes.

Antidepressant medication therapy is not a cure for depression. These drugs are effective in treating some of the symptoms of depression, but cannot change underlying contributions to depression in patients’ lives. Studies have shown, and many experts believe, that antidepressant medications often work best in combination with psychotherapy lasting for several months. On their own, antidepressant medications are important, especially in treating patients who have difficulty, or are hesitant in, accessing a psychotherapy professional.

When initiating an antidepressant drug regimen, encourage the patient to be patient as it may take 4-8 weeks for the drug therapy to be fully effective. In addition, side effects may appear in the beginning, but most improve over time. Follow up visits are important to assess treatment response. Finally, consider changes in the drug regimen if significant improvement in symptoms does not occur after six weeks.

First Line Treatment: SSRI, TCA, SNRI, NRI, DA

Second Line Treatment: SSRI and a second anti-depressant; addition of atypical anti-psychotic

### MEDICATION THERAPY OPTIONS FOR DEPRESSION
